StringOperations Documentation

The StringOperations class has methods for performing useful string operations. Documentation for each method is provided below.

public static int findSubstring(String str, String sub)

Purpose:
Searches a string for the first occurrence of a substring, and returns the position at which the substring is found.
Parameters:
str – The string being searched. Must be non-null
sub – The substring being searched for. Must be non-null
Returns:
The zero-based index at which the first occurrence of sub was found within str, or -1 if sub does not appear within str
